Programming Techniques (1)

Programming With Exceptions

- Use of exceptions pervades an entire application and cannot be localized.
 - —An exception can be propagated up the call stack.
 - -Each exception "terminates" the respective current block.
- Throwing an exception is easy; writing code that uses a throwing function is hard.

—We will see why.

Programming Techniques (2)

Programming With Exceptions

- o Exceptions can pop up everywhere.
- Before exception handling it was impossible to indicated errors in constructors, overloaded operators, and destructors.
 - -Either they have no return code, or
 - -the return code is used for purposes other than error reporting, e.g. operator chains

```

Exceptions Everywhere ...

```
A typical C idiom:
while (a[i++] = b[j++])
```

- **a** and **b** can be of different types, e.g. the STL containers **vector** and **deque**.
- o **i** and **j** can be of different iterator types.
- Assignment can be overloaded for the element type.
- Converting constructors and cast operators can be involved.

Programming Techniques (4)

Exceptions Everywhere ...

```
vector<string> a; deque<char*> b;
vector<string>::iterator i; deque<char*>::iterator j;
```

while (a[i++] = b[j++])

actually is a sequence of functions calls each of which might throw an exception:

```
while ((a.operator[](i.operator++()))
    .operator=(string
    (b.operator[](j.operator++()))))
```

Programming Techniques (5)

Exceptions Everywhere ...

A typical C idiom: while (a[i++] = b[j++])

If an exception appears ...

o where did it come from?

The order of evaluation of function arguments is unspecified. If an exception appears ...

o what are the current values of **a**, **b**, **i**, and **j**?

Programming Techniques (6)

Programming With Exceptions

- o Exceptions cannot be ignored.
- We must cope with them when they occur, even if we are not willing to handle them.
 - -An exception terminates the current block,
 - -current operations are aborted before they are finished,
 - -objects might be left in inconsistent states, and
 - -acquired local resources might not be released.

Programming Techniques (8)

Exceptions cannot be ignored ...

```
template <class T>
void Stack<T>::push(const T& elem)
{ mutex_.acquire();
    v_[top_] = elem;
    top_++;
    mutex_.release();
}
In case of an exception the mutex object would not be
    released.
    __a typical problem with dynamically acquired
    resources

```
void use file (const char* filnam)
{ FILE* fil = fopen(filnam,"w");
 // use the file fil
  fclose(fil);
}
```

In case of an exception the file would not be closed.

Resource Acquisition

```
void use file (const char* filnam)
{ FILE* fil = fopen(filnam,"w");
    try {/* use the file fil */}
    catch (...)
    { fclose(fil);
       throw;
    }
    fclose(fil);
}

Exception Handling
```

Programming Techniques (12)

• All exceptions are caught and the file is closed, i.e. the resource is released, in the **catch** block.

-Error-prone, because it can get rather complicated if numerous resources are acquired and released.

• A more elegant solution: Wrap resources into classes, and use constructors for acquisition and destructors for release.

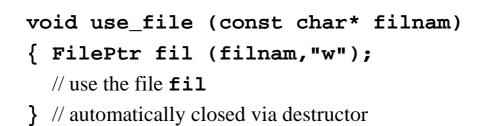

-Destructors are called even when exceptions appear and this way release is guaranteed.

Programming Techniques (16)

```
class Thing { /* ... */ };
void func ()
{ Thing* tp = new Thing;
    // ...
    delete tp;
}
```

In case of an exception the **Thing** would not be deleted.

The auto_ptr Class

- Use **auto_ptr** for dynamically allocated, local objects.
- An **auto_ptr** stores a pointer to an object obtained via new and deletes that object when it itself is destroyed (such as when leaving block scope).

Using auto_ptr

```
class Thing { /* ... */ };
void func ()
{ auto_ptr<Thing> tp(new Thing);
    // ...
}
```

auto_ptr takes care of deleting **Thing** when leaving the function body (either on normal return or when an exception appears).

```

```

The auto_ptr Class

```
template<class X> class auto_ptr {
private:
   X* ptr_;
public: // construct/destroy:
   explicit auto_ptr(X* p =0) throw()
   : ptr_(p) {}
   ~auto_ptr() throw() { delete ptr_; }
};
```

Exception Handling

The auto_ptr Class

The **auto_ptr** provides a semantics of strict ownership.

- An **auto_ptr** owns the object it holds a pointer to.
- Copying an **auto_ptr** copies the pointer and transfers ownership to the destination.
- If more than one **auto_ptr** owns the same object at the same time the behavior of the program is undefined.

```
Exception Handling
```

last update: 06.11.2005 ,11:35 © Copyright 1995-98 by Angelika Langer. All Rights Reserved.

Programming Techniques (21)

Transfer of Ownership

```
auto_ptr<Thing> tp(new Thing);
auto_ptr<Thing> tp2 = tp;
```

- After assignment tp2 owns the object, and tp no longer does.
- tp is empty; deleting tp would not delete any Thing object anymore.

Exception Handling

Programming Techniques (22)

Transfer of Ownership

```
Thing* p = new Thing;
auto_ptr<Thing> tp1(p);
auto_ptr<Thing> tp2(p);
```

Misuse:

• More than one **auto_ptr** owns the **Thing** object.

Programming Techniques (23)

The auto_ptr Class

```

public: // give up ownership:
   X* release() throw()
   { X* tmp = ptr_; ptr_ = 0; return tmp; }
public: // copy constructor:
   auto_ptr(auto_ptr& a) throw()
   { ptr_(a.release()); }
};

};
```

Exception Handling

Programming Techniques (27)

The auto_ptr Class

The uses of **auto_ptr** include

- providing temporary exception-safety for dynamically allocated memory,
- passing ownership of dynamically allocated memory to a function, and
- o returning dynamically allocated memory from a function.

auto_ptr cannot be used as the element type of the STL containers.

• **auto_ptr** does not meet the CopyConstructible and Assignable requirements for STL container elements.

Using auto_ptr

```
Conventional pointer member: Alternative using auto_ptr:

class X {

T* pt_; class X {

auto_ptr<T> apt_;

public: pt_(new T) {}

~X(){ delete pt_; }

}; };

Exceptions in new Expressions

What happens if \mathbf{x} 's constructor throws?

X* p1 = new X; X* p2 = new X[256];

The memory allocated by the **operator new()** is freed. No memory leak!

Exception Handling last update: 06.11.2005, 11:35 ° Copyright 1995 98 by Angelika Langer. All Rights Reserved. Programming Techniques (32)

Exceptions in Constructors

- Constructors are a special case. If an exception propagates from an constructor ...
- the partial object that has been constructed so far is destroyed.
 - -If the object was allocated with **new** the memory is deallocated.
- only the destructors of fully constructed subobjects are called.

—The destructor of the object itself is not called.

Programming Techniques (33)

Exceptions in Constructors

```
class X {
    S s_; T t_;
public:
    X(const S& s, const T& t)
    : s_(s), t_(t) // assume exception from copy ctor of T
    {}
    ~X(){}
};
Destructor for t_ is not called, because it was not constructed.
Destructor for s_ is called (fully constructed subobject).
Destructor ~X() is not called.
```

last update: 06.11.2005 ,11:35 © Copyright 1995-98 by Angelika Langer. All Rights Reserved.

Programming Techniques (34)

Exceptions in Constructors

- If a resource is obtained directly (not as part of a subobject) a resource leak can occur.
- Only the allocation and construction of subobjects is reverted in case of an exception.
 - —No automatic cleanup for already performed initializations.

Exception Handling

Programming Techniques (35)

Exceptions in Constructors

```
class X {
   S* ps_; T* pt_;
public:
   X() : ps_(new S), pt_(new T) {}
   ~X(){ delete pt_; delete ps_; }
};
Assume an exception is thrown from the constructor of T.
Allocation of the temporary T object fails. Memory allocated with
   new T is deallocated; ~T() is not called.
The pointers ps_ and pt_ are destroyed.
The construction of X fails; the destructor ~X() is not called.
The object ps_ points to is never deleted.
```

Exceptions from a Constructor Initializer List

How can we catch exceptions from a constructor initializer list?

```
X::X() try : ps_(new S), pt_(new T)
{}
catch(...)
{ // problem: don't know what happened
    // exception can stem from ctor initializer or function body
}
```

Exception Handling

last update: 06.11.2005 ,11:35 © Copyright 1995-98 by Angelika Langer. All Rights Reserved.

Programming Techniques (37)

Exceptions in Constructors

A solution:

• Not ideal; error-prone in case of numerous dynamically acquired resources.

```
X::X(){
 try {ps_ = new S;}
 catch(...)
 { throw; /* do nothing, because no subobject is constructed yet */ }
 try {pt_ = new T;}
 catch(...)
 { delete ps_; }
}
```

Exception Handling

Exceptions in Constructors

Another solution:

• Initialize pointers to 0, so that you can safely delete them.

```
X::X() : ps_(0), pt_(0)
{ try { ps_ = new S; pt_ = new T; }
    catch (...)
    { delete pt_;
        delete ps_; // reverse order
        throw;
    }
}
```

```
Exception Handling
```

last update: 06.11.2005 ,11:35 © Copyright 1995-98 by Angelika Langer. All Rights Reserved.

Programming Techniques (39)

Exceptions in Constructors

Yet another solution: Use **auto_ptr**.

```
class X {
  auto_ptr<S> aps_; auto_ptr<T> apt_;
public:
  X() : aps_(new S), apt_(new T) { }
  ~X() { }
};
Assume an exception is thrown from the constructor of T.
The subobject apt_ is not created and need not be destroyed.
The subobject aps_ is destroyed; the destructor of aps_ destroys
  the object aps_ points to.
```

Rules

- o Avoid resource leaks.
- Use "resource acquisition is initialization" for dynamically acquired resources.

-Wrap resources into a class, acquire in its constructor, and release in its destructor.

• Use **auto_ptr** for dynamically allocated memory.

Programming Techniques (42)

Destructors and Exceptions

A destructor can be called

- as the result of normal exit from a scope, a
 delete expression, or an explicit destructor call, or
- during stack unwinding, when the exception handling mechanism exits a scope containing an object with a destructor.
 - —If an exception escapes from a destructor during stack unwinding **::std::terminate()** is called.

Rules

- Do not catch any exceptions if you do not know how to handle them.
 - -Rewrite functions to preserve state instead of adding catch clauses.
 - —If you cannot ignore propagated exceptions, use a catch-all clause.
 - —If you get stuck, call terminate() instead of abort().

Programming Techniques (46)

Statement Rearrangement

```
Typical C++ code corrupts object state if assignment fails:
    array[i++] = element; // >>
    Exception handling is expensive. Don't do this:
    try { array[i++] = element; } // >>
    catch(...) { i--; throw; }
    Rewrite to:
    array[i] = element; // >>
    i++;
```

Rules

Exception Handling

- Do not hide exception information from other parts of the program that might need them.
 - —Always rethrow the exception caught in a catch-all clause.
 - -Re-throw a different exception only to provide additional information.

Hiding Exceptions

```
template <class T> class Stack<T> {
public:
    struct AllocationError : public bad_alloc
    { size_t stack_size; } // has additional information
    Stack& operator=(const Stack& rhs)
    { //...
    try { new_buffer = new T[new_elems]; }
    catch(...)
    { throw AllocationError(new_elems); }
    //...
    };

Programming Techniques (49)

Hiding Exceptions

```
try { new_buffer = new T[new_elems]; }
catch(...)
{ throw AllocationError(new_elems); }
What if T::T() throws an exception?
A caller's handler that is prepared to handle the
```

constructor exception does not get a chance to do so, and a handler for the allocation error might try to solve the wrong problem.

Hiding Exceptions

A possible solution:

```
new_buffer = new(nothrow()) T[new_elems];
if (new_buffer == 0)
throw AllocationError(new_elems);
```

Possible Exception Sites

```
delete[] v_;
v_ = new T[nelems_ = s.nelems_]; // >>
// definitely a problem here!
```

Old array is deleted. Allocation of new array failed. Pointer **v**_ is left dangling. The **Stack** destructor will try to delete **v**_ => disaster!

The Stack object is not even destructible any more!

Programming Techniques (66)

```
delete[] v_;
v_ = new T[nelems_ = s.nelems_]; //>>
for (top_=0;top_<s.top_;top_++)
    v_[top_] = s.v_[top_]; //>>
    // definitely a problem here!
```

Stack object is invalid because copy has been done only partially. Since the old Stack data is already deleted, we cannot leave the Stack in its original state.

A solution: Define a NIL object, which represents a valid, but not usable value. (NULL pointer, zero-size string, emtpy stack)

Keep Stack destructible

```
delete[] v_;
v_ = new T[nelems_ = s.nelems_]; //>>
// Pointer v_ is left dangling. The Stack destructor will try to delete
 v_ => disaster!
T* tp = v_;
v_ = 0;
delete tp;
v_ = new T[nelems_ = s.nelems_]; //>>
// The Stack destructor can safely delete v_.
```

Leave Stack in a valid NIL state

```
v_ = new T[nelems_ = s.nelems_]; // >>
for (top_=0;top_<s.top_;top_++)
    v_[top_] = s.v_[top_]; // >>
// Stack object is invalid because copy has been done only partially.
v_ = new T[s.nelems_]; // >>
top_=0; nelems_=0;
for (size_t i=0;i<s.top_;i++)
    v_[i] = s.v_[i]; // >>
nelems_ = s.nelems_; top_ = s.top_;
// Stack object is NIL, i.e. empty, if copy fails.
```

Leave Stack untouched

```
v_ = new T[nelems_ = s.nelems_]; // >>
for (top_=0;top_<s.top_;top_++)
    v_[top_] = s.v_[top_]; // >>
// Stack object is invalid because copy has been done only partially.
new_buffer = new T[s.nelems_]; // >>
for (size_t i=0;i<s.top_;i++)
    new_buffer[i] = s.v_[i]; // >>
swap(v_,new_buffer); delete [] new_buffer;
nelems_ = s.nelems_; top_ = s.top_;
// Stack object is not modified until copy is successfully completed.
```

Rule

Perform critical operations through temporaries.

- Modify the object only after successful completion.

Leave valid NIL objects if you can't preserve the original state.

- Set object state to NIL before a critical operation and set to final value afterwards, i.e. only in case of success.

Keep your objects destructible.

- -Do not leave dangling pointer in your objects.
- Delete pointers through temporaries.

Programming Techniques (71)

Eliminate Resource Leak

The memory allocated for **new_buffer** is not deallocated. => resource leak!

Programming Techniques (72)

An auto_array_ptr Class

- Implement an auto pointer that holds a pointer to an array of elements.
- Solve the resource leak problem in the Stack assignment using the auto array pointer.

Rules

- Leave your object in the state it had when the function was entered.
- Perform critical operations through temporaries.
- Leave valid NIL objects if you can't preserve the original state.
- Keep your objects destructible.
- Use auto pointers and "resource acquiition is initialization" to avoid resource leaks.
- o Avoid side effects in critical operations.

Exception Safety

- A user of a function is interested in the guarantees the function can give when exceptions are propagated.
- Document not only the pre- and post conditions and the "normal" effect of a function, but also its exception safety guarantees.

Exception Safety Guarantees

Level 0: No guarantee.

Part of the data the function tried to modify might be lost or corrupted. Access to the data might cause a program crash.

Level 1: Destructibility.

Part of the data might be lost or in an incosistent state. It is not possible to safely to access to the data. However, it is guaranteed that the data can be destroyed.

Level 2: No resource leaks.

All objects that the function modifies have their destructors called, either when f() handles the exception or when those objects' destructors are called.

Exception Handling

Programming Techniques (81)

Exception Safety Guarantees

Level 3: Consistency.

All objects are left in a consistent state, not necessarily the state before f() was entered, and not necessarily the state after normal termination. All operations on the data have well-defined behavior. No crashes, no resource leaks, safe access.

Level 4: Full commit-or-rollback.

All objects are left in the state they had before execution of f(). All data values are restored to their previous values.
